

Principle of UPS Distribution Box in Computer Room

Overview

The three general categories of modern UPS systems are on-line, line-interactive and standby:

- An online UPS uses a "double conversion" method of accepting AC input, to DC for passing through the (or battery strings), then inverting back to 120 V/230 V AC for powering the protected equipment. The low-power 1-3KVAUPS uninterruptible power supply is mainly used in IT equipment, using voltage and frequency stabilization technology to correct voltage and frequency, protect computers and other equipment from damage, and more importantly, ensure that data is not lost . A UPS system is a backup power system that provides immediate, uninterrupted power to critical equipment when the primary power source fails or becomes unstable. Unlike generators, which take several seconds to start, a UPS system provides instantaneous power with no delay. Energy Storage: UPS systems use batteries, flywheels, or supercapacitors to store energy for use during power interruptions. A UPS system is an autonomous source of alternate power that is used to supply sensitive electronic loads such as computer centers, telephone exchanges and many industrial-process control and monitoring systems. From plug and receptacle charts and facts about power problems to an overview of various UPS topologies and factors affecting battery life, you'll find a wealth of pertinent resources designed to help you develop the optimum.
