

Relay Protection Optimization and Adjustment

Overview

Focusing on directional overcurrent relays, the study examines optimization-based methods for tuning key relay parameters, which include the pickup current and the time multiplier setting, to minimize the total relay operating times and ensure reliable protection. To improve the reliability and sensitivity of multi-level relay protection in distribution networks with distributed power sources, this study designs an adaptive setting strategy optimization method. This method fully analyzes the impact of distributed generation access on the dynamic. Ergo, this paper presents an ensemble that combines the independent factor evaluation (IFE) and quantum genetic optimization (QGO) models to further optimize the performance of relays according to their distributed tuning environment. By designing and implementing relay coordination schemes, these professionals ensure that faults are detected promptly, isolated, and that system stability is maintained.
