

# **The core switch connects to two servers**

## Overview

---

It connects multiple distribution layer switches and provides the fastest possible transport between different physical buildings, server farms, and data centers. Fault tolerance is absolute here; if the core goes down, the entire network fails. The primary transmission and routing of data signals take place at the core layer only. What is the advantage for having separate access switch and then from access switch uplink to the core Please advise Thanks in advance You might have two cores so the access switch can take a failure on the core. The Aruba ESP Two-Tier Data Center can be configured using Aruba Central or Aruba Fabric Composer (AFC). The Two-Tier architecture uses Layer 2 multi-chassis links between a VSX pair of core switches and a set of server access switches. In large organizations, networks become complex, exchanging massive amounts of data.
